Announcements

◆ Mid-Term 1

- ◆ Will hand out next Tuesday, due by Friday

Poor programming practices

```
def stateEquation(theta):  
    """ *** """  
  
    value = np.tan(theta) - np.sin(theta) - m*g/(2.0*k*L)  
    return value  
  
# main program  
#  
  
# create data points with radians but plot using degrees  
theta = np.linspace(0,np.pi/2,1000)  
  
m = 5  
L = 0.3  
k = 1000  
g = 9.81  
sPoints = s(theta)  
plt.plot(theta,sPoints)
```

**values rely
on later and
non-local
declarations**

better programming practice

```
def stateEquation(theta):
    """ [function documentation here] """

    m = 5          # [kg]    mass of object
    L = 0.3        # [m]    half distance between support
    k = 1000       # [N/m]   spring constant
    g = 9.81      # [N/kg]  acceleration due to gravity

    value = np.tan(theta) - np.sin(theta) - m*g/(2.0*k*L)
    return value

# main program
#

# create data points with degrees but pass data as radians
theta = np.linspace(0, 89, 90)

sPoints = s( np.radians( theta ) )
plt.plot( theta, sPoints )
plt.show()
```

**better to have
variables in
local scope**

Even better programming practice

```
class stateParameters:
    """ parameter constants for the two springs equation """
    m = 5          # [kg]    mass of object
    L = 0.3        # [m]    half distance between support
    k = 1000       # [N/m]   spring constant
    g = 9.81       # [N/kg]  acceleration due to gravity

def stateEquation(theta, par):
    """ plotting function: tan(x) - sin(x) - mg/(2kL) """
    value = np.tan(theta) - np.sin(theta) - par.m*par.g/(2.0*par.k*par.L)
    return value

# *****main program*****
# create data points with degrees but pass data as radians to function
theta = np.linspace(0, 89, 90)

statePoints = stateEquation( np.radians(theta), stateParameters )
plt.plot(theta, statePoints)
plt.show()
```

**better to have
variables
wrapped in an
object container**

Procedural Programming

```
#!/usr/bin/env python
```

```
"""
```

```
* factorial  
* PHY4151  
*  
* Created by Paul Eugenio  
*  
* This program was created to illustrate the basic  
* components of procedural-type programming  
*  
"""
```

```
from __future__ import division, print_function
```

```
#  
# main program
```

```
number = int(raw_input("Enter value for factorial "))  
n, result = number, 1
```

```
# calculate factorial of n  
while n > 0:  
    result = n * result  
    n = n - 1
```

```
print("The factorial of the number", number, "is", result)
```

Post processing statements

The main body of the program

A Better Procedural Program

```
#!/usr/bin/env python
"""
* factorial
* PHY4151
*
* Created by Paul Eugenio
*
* This program was created to illustrate the basic
* components of procedural-type programming
*
"""
from __future__ import division, print_function

def factorial(aNumber):
    result = 1
    if aNumber > 0:
        result = aNumber* factorial(aNumber - 1)

#
# main program

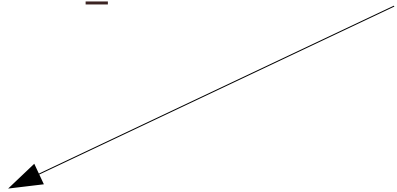

number = int(raw_input("Enter value for factorial "))
result = factorial( number )

print("The factorial of the number", number, "is", result)
```

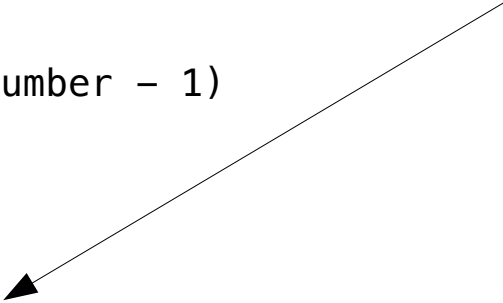

Post processing statements

declaration of the factorial() function

The main body of the program

A photograph of two white ducks standing in a snowy field. The ducks are facing each other, with their heads tilted towards one another. The background is a vast, flat expanse of snow with some sparse, dry grass visible. The overall scene is bright and wintry.

Object-Oriented Programming

Python object-oriented programming syntax
[not covered in course text]

Defining Object via a Class Declaration

- ◆ A class is a template for containing
 - ◆ Data/objects/variables
 - ◆ often hidden from user
 - ◆ Member functions/Methods
 - ◆ Constructors, Destructors, Getters, & Setters

- ◆ Scope

- ◆ keeping it all local

Python has class

Python is an object-oriented programming language

```
# Defining a class
class class_name:
    [statement 1]
    [statement 2]
    [statement 3]
    [etc.]
```

A “class” defines an object as a container for data (variables) and methods (functions)

Example: A Circle

Class Definition of Simple Circle

```
class Circle:
    def __init__(self, aRadius=1):
        self.radius = aRadius

    def area(self):
        return np.pi*self.radius**2

    def circumference(self):
        return 2*np.pi*self.radius

    def __add__(self, other):
        return Circle(self.radius + other.radius)

    def print(self):
        print("Hello, I am a circle")
        print("my radius is",self.radius)
        print("My area is", self.area())
        print("My circumference is", self.circumference())
        print()
```

Special Methods

constructor

```
def __init__(self, aRadius=1):  
    """ Default constructor sets unit radius """  
    self.radius = aRadius
```

operator overloading

```
def __add__(self, other):  
    """  
    Add circles where  $C = A + B$  equals a circle  
    with radius equal to the sum of the two radii  
    """  
    return Circle(self.radius + other.radius)
```

```
A = Circle(3)  
B = Circle()  
C = A + B          # C is a circle of radius 4  
...
```

Utilizing a Circle Object

```
hpc-login 213% circle.py
Hello, I am a circle
my radius is 1
My area is 3.14159265359
My circumference is 6.28318530718

Hello, I am a circle
my radius is 3
My area is 28.2743338823
My circumference is 18.8495559215

Area of circle C is 50.2654824574

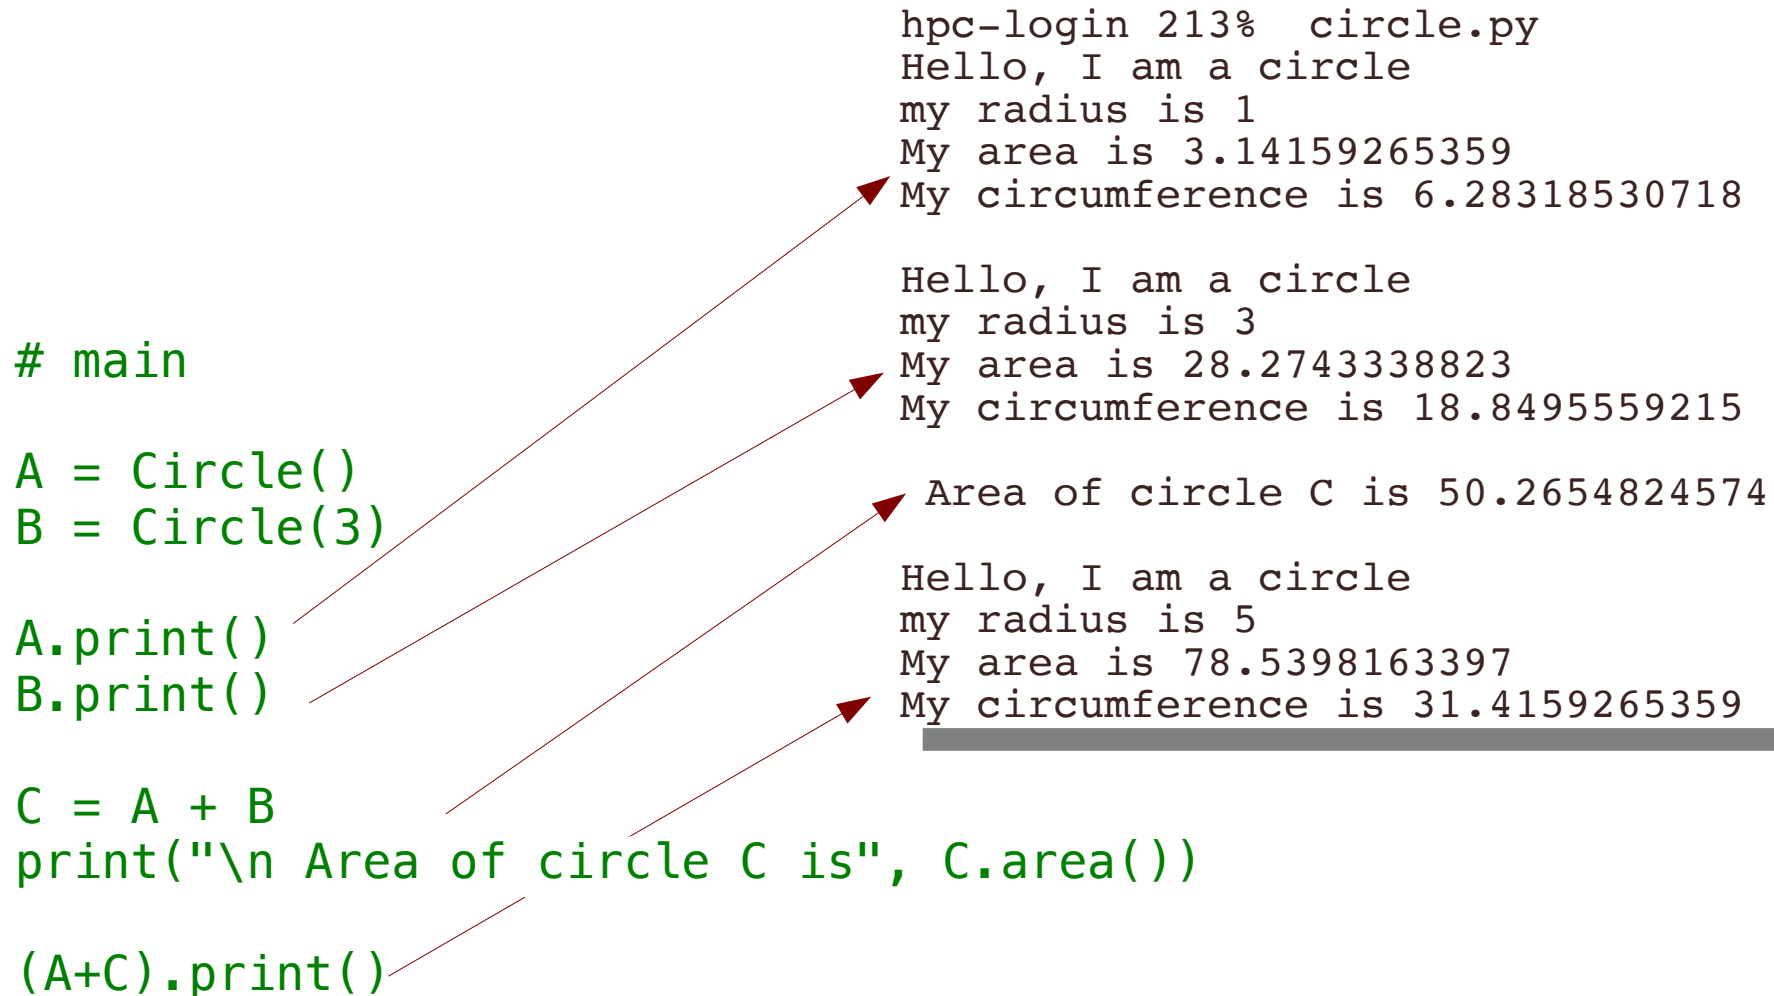

Hello, I am a circle
my radius is 5
My area is 78.5398163397
My circumference is 31.4159265359
```

```
# main
A = Circle()
B = Circle(3)

A.print()
B.print()

C = A + B
print("\n Area of circle C is", C.area())

(A+C).print()
```

OOP Promotes Bottom-up Programming

2D Vector Procedural Approach

```
""" Simple 2D vector """
```

```
# data list for x,y  
Vector = [0.0, 0.0]
```

```
# modify data value
```

```
Vector[0] = 1.0      # x value  
Vector[1] = 2.0      # y value
```

```
def addVect2D(V1, V2):
```

```
    Vsum = []  
    Vsum += V1[0] + V2[0]    # add x's  
    Vsum += V1[1] + V2[1]    # add y's  
    return Vsum
```

```
def multVect2D(V1, V2):
```

```
    return sqrt(V1[0]*V2[0] + V1[1]*V2[1])
```

```
def printVect2D( V ):
```

```
    print("vector(x,y) is (", V[0], ",", V[1], ")")
```

```
# main
```

```
P1 = [1.0, 1.0]
```

```
P2 = [2.0,2.0]
```

```
P = addVect2D( P1, P2 )
```

```
Q = multVect2D( P, P2 )
```

```
printVect2D(P1)
```

```
printVect2D(P2)
```

```
printVect2D(P)
```

```
printVect2D(Q)
```

OOP Example: Vector2D

```
class Vector2D:
```

```
    """ Vector2D Object declaration """
```

```
    def __init__(self, aX=0.0, aY=0.0):
```

```
        """ Default constructor """
```

```
        self.x, self.y = aX, aY
```

Member functions
& variable data

```
    def r(self) :
```

```
        """ Polar coordinate magnitude """
```

```
        return numpy.sqrt( self.x()2 + self.y()2 )
```

```
    def theta(self) :
```

```
        """ Polar coordinate angle """
```

```
        return numpy.atan2( self.y(), self.x() )
```

```
    def __add__(self, other):
```

```
        """ Operator overload for vector addition """
```

```
        return Vector2D(self.x() + other.x(), self.y() + other.y())
```

```
    def __mul__(self, other):
```

```
        """ Operator overload multiplication for dot product """
```

```
        return numpy.sqrt( self.x() * other.x() + self.y() * other.y() )
```

```
    def print(self):
```

```
        """ Vector2D print vector information """
```

```
        print("vector(x,y) is (", self.x(), ",", self.y(), ")")
```

OOP Example: Vector2D

```
# main
```

```
P1 = Vector2D()
```

```
P2 = Vector2D(1.0,1.0)
```

```
P3 = Vector2D(2.0,2.0)
```

```
P1.print()
```

```
P2.print()
```

```
P3.print()
```

```
P1 = P2 + P3
```

```
P1.print()
```

```
hpc-login 55% myvectors.py
```

```
vector(x,y) is (0,0)
```

```
vector(x,y) is (1,1)
```

```
vector(x,y) is (2,2)
```

```
vector(x,y) is (3,3)
```

```
hpc-login 56%
```

Data Encapsulation

```
class Vector2D:
```

```
    """ Vector2D Object declaration """
```

```
    def __init__(self, aX=0.0, aY=0.0):  
        self.__x = aX  
        self.__y = aY
```

```
    def x(self):  
        return self.__x
```

```
    def y(self) :  
        return self.__x
```

```
    def r(self) :  
        return math.sqrt( self.x()2 + self.y()2 )
```

```
    def theta(self) :  
        return math.atan2( self.y(), self.x() )
```

using two "_" makes
the data private

this is data encapsulation

```
    def __add__(self, other):  
        """ ** """  
        return Vector2D(self.x() + other.x(), \  
                          self.y() + other.y())
```

```
    def __mul__(self, other):  
        """ ** """  
        return sqrt( self.x() * other.x() + \  
                      self.y() * other.y() )
```

```
    def print(self):  
        """ ** """  
        print("vector(x,y) is (", self.x(), ",", \  
              self.y(), ")")
```

** for brevity docstrings have been omitted

Data Encapsulation

If we want to represent the `Vector2D` data by (r, θ) rather than by (x, y) then very little changes are needed in the class definition and **NO** changes will be needed in the user code.

Vector2D with encapsulated polar data

```
class Vector2D:
    """ Vector2D Object declaration """

    def __init__(self, aX=0.0, aY=0.0):
        self.setR( numpy.sqrt(aX**2 + aY**2) )
        self.setTheta( numpy.arctan2(aY, aX) )

    def setR(self, aR):
        self.__r = aR

    def setTheta(self, aTheta):
        self.__theta = aTheta

    def x(self):
        return self.r() * numpy.cos( self.theta() )

    def y(self) :
        return self.r() * numpy.sin( self.theta() )

    def r(self) :
        return self.__r

    def theta(self) :
        return self.__theta
```

using two "_" makes
the data private

this is data encapsulation

```
def __add__(self, other):
    """ ** """
    return Vector2D(self.x() + other.x(), \
                    self.y() + other.y())

def __mul__(self, other):
    """ ** """
    return sqrt( self.x() * other.x() + \
                 self.y() * other.y() )

def print(self):
    """ ** """
    print("vector(x,y) is (", self.x(), ",", \
          self.y(), ")")
```

** for brevity docstrings have been omitted

program operates as before

```
# main
```

```
P1 = Vector2D()
```

```
P2 = Vector2D(1.0,1.0)
```

```
P3 = Vector2D(2.0,2.0)
```

```
P1.print()
```

```
P2.print()
```

```
P3.print()
```

```
P1 = P2 + P3
```

```
P1.print()
```

```
hpc-login 55% myvectors.py
```

```
vector(x,y) is (0,0)
```

```
vector(x,y) is (1,1)
```

```
vector(x,y) is (2,2)
```

```
vector(x,y) is (3,3)
```

```
hpc-login 56%
```

Extending Objects: Vector3D

```
class Vector3D:  
    def __init__(self, aX, aY, aZ):  
        self.__V2D = Vector2D(aX, aY)  
        self.__z = aZ  
  
    def __add__(self, other):  
        ...
```

Vector3D has a Vector2D

Inheritance: Vector3D

```
class Vector3D(Vector2D):
    def __init__(self, aX, aY, aZ):
        Vector2D.__init__(self, aX, aY)
        self.__z = aZ

    def z(self):
        return self.__z

    def __add__(self, other):
        ...
```

Point3D *is a* Point2D

Other Special Methods

Construction

a.__init__(self, args)

a.__del__(self)

a.__call__(self, args)

a.__str__(self)

a.__add__(self, b)

a.__sub__(self, b)

a.__mul__(self, b)

a.__truediv__(self, b)

a.__pow__(self, b)

a.__lt__(self, b)

a.__gt__(self, b)

a.__le__(self, b)

a.__ge__(self, b)

a.__eq__(self, b)

a.__ne__(self, b)

a.__bool__(self)

a.__len__(self)

a.__abs__(self)

...

Meaning

constructor: $a = A(\text{args})$

destructor: `del a`

call as function: $a(\text{args})$

pretty print: `print a, str(a)`

$a + b$

$a - b$

$a * b$

a / b

$a ** p$

$a < b$

$a > b$

$a \leq b$

$a \Rightarrow b$

$a == b$

$a != b$

boolean expression, as in `if a:`

length of a: `len(a)`

`abs(a)`

Let's get working
